CHAPTER 402

STRUCTURE SIZE AND TYPE

402-1.0 DEFINITIONS

402-2.0 NOTATIONS

402-3.0 INTRODUCTION

The basic objective of this Chapter is to select the most appropriate structure type and configuration for the given project site conditions. This selection process is a critical event in the project development. The decision made in this process will impact the detailed structure design phase, construction costs, and maintenance costs over the life of the structure. The designer shall perform the structure size and type analysis based on the information provided in this Chapter, available resources and through the use of sound engineering theory, practice, and judgment. The results from the analysis will permit final design of the structure through the rest of the project development.

This Chapter describes available resources, abbreviated submission requirements for Stage 1 Review, as it relates to the structure size and type process, and the use of evaluation factors and design criteria to determine the most appropriate structure size and type for the given project site. This information is provided throughout this Chapter while referencing applicable figures, design references, and other *Manual* Chapters. The design memoranda can include additional applicable information for use in the structure size and type analysis.

Design factors shown in this Chapter will depend primarily on project classification as 3R or 4R. The Engineer's Assessment will be based on the direct use of 3R or 4R criteria and the appropriate geometric design tables. See Chapters 53 and 55 for additional information.

402-4.0 SUBMISSION REQUIREMENTS

The structure size and type analysis is performed as part of the Stage 1 design phase. The Stage 1 design phase shall be concurrent with or following the design phase for the roadway. It is critical for the structure design to coordinate with the roadway design during the structure size and type process.

The Stage 1 design phase is described in Chapter 14. A brief overview of the specific requirements of the Stage 1 Submission as it relates to the structure size and type analysis is described below.

402-4.01 Design Information

Applicable project and design information shall be presented in the form of a report and included as part of the structure size and type analysis within the Stage 1 Submission. The structure size and type report shall provide a brief description of the project and include narratives discussing the following.

402-4.01(01) Discussion of Design Factors

The design factors that contribute to the structure size and type analysis shall be discussed within the report narrative. All existing conditions, such as existing structure, natural obstacles, utilities, unusable soil conditions, stream characteristics, traffic maintenance, hydraulic parameters, and clearance requirements shall be known at the time of the structure size and type selection process.

Design and evaluation factors are explained below. These factors are not all inclusive of the factors encountered. Each project is unique and dependent on specific considerations, restraints, and conditions that shape the development of the project. Such factors can include geometry and hydraulic considerations, environmental restrictions, right-of-way restraints, corridor consistency, aesthetics, construction costs, life cycle costs, maintenance of traffic, geotechnical considerations, and others. These applicable and specific factors that are relevant to the structure size and type analysis performed shall be discussed within the report narrative.

402-4.01(02) Deviation from the Initial Engineer's Report

An initial Engineer's Assessment is completed prior to the structure size and type phase. Deviation from the original Assessment will require an analysis to substantiate the need for the change. The structure size and type narrative will include the justification for changes to the project cost.

402-4.01(03) Discussion of Alternates

A structure size and type analysis consists of investigating pertinent and logical structure types and sizes that fit the specific project site and its parameters. Investigation into multiple alternates is encouraged so that a true best alternate can be chosen to be carried through final design. Typical alternates that can be investigated are a spill-through type configuration versus a bridge utilizing retaining walls at the end bents, a large-girder single-span bridge versus a three-span bridge, a small single-span bridge versus a three- or four-sided structure, or other possible configuration comparisons. Superstructure-type alternatives such as, but not limited to, reinforced concrete slab, prestressed-concrete beams, steel girders, post-tensioned structures, steel U-tubs, or a post-tensioned slab shall be considered. It is not necessary that all above types be evaluated, but a reasonable alternative shall be included.

These different structure alternates shall be compared using the applicable evaluation factors, with the primary consideration being cost. The advantages and disadvantages of each alternate shall be discussed, indicating the primary reasons for the selection of the recommended structure size and type.

401-4.02 Economic Analysis

An economic analysis shall be performed as part of the structure size and type analysis in order to determine the initial construction cost, the life cycle cost, and other costs associated with each alternate investigated. This economic analysis shall be included as part of the structure size and type analysis within the Stage 1 submission.

The purpose of this section is to provide the process to be used in evaluating the economics of various structural alternatives with the goal of selecting the most suitable alternative to proceed to the final design phase. Cost comparisons required at the Structure Size and Type phase shall not be completed with only the initial capital cost considerations. The lowest initial capital cost does not always lead to lowest cost for the owner. Cost comparisons for structural alternatives shall, in addition to initial capital costs, include costs associated with long-range considerations. Cost comparisons for each alternative shall consider all aspects that can impact initial and future costs such as;

1. the cost associated with the complexity of future inspections;
2. future maintenance and life cycle costs;
3. operating costs;
4. the availability and familiarity of the structure type with local contractors, fabricators and suppliers;
5. the impacts of the structure alternative to the roadway approaches and retaining walls;
6. the impacts to utilities;
7. costs associated with right-of-way requirements;

8. the costs required for additional environmental mitigation for a specific alternate; and
9. the costs associated with unusual site conditions or constraints.

All of these factors shall be calculated and included in the cost estimate for each structure alternative in order to properly identify the correct alternative to be chosen for the final design phase.

402-4.02(01) Construction Cost

The economic analysis shall compare the estimated construction cost to complete the project for each alternate investigated. To determine relative construction costs of each alternate, all quantities independent of the alternates shall be computed. Quantities that are considered equal for each alternate need not be considered, as they do not contribute to the comparative construction cost computed.

Current construction prices in materials and construction methods shall be obtained in order to obtain accurate costs.

402-4.02(02) Life-Cycle Cost

Long-term life-cycle costs of each alternate shall be considered in the overall structure size and type analysis. Different structure types and elements have different rehabilitation cycles or replacement schedules. These factors can affect the overall cost of the structure and therefore the selection of the recommended alternate.

402-4.02(03) Summary

The economic analysis performed will yield the respective construction costs, life-cycle costs, and overall costs of each alternate investigated. This economic analysis shall be included as part of the structure size and type analysis. A discussion of the recommended alternate, largely based on this analysis, shall be provided within the structure size and type report.

402-4.03 Level One Checklist and Computations

A Level One Checklist, including computations, shall be developed for the roadway and bridge elements. The apparent Level One and Level Two design exceptions shall be indicated. See Section 40-8.02(01) for additional information regarding Level One Checklist requirements.

402-4.04 Plans

Stage 1 plans shall be submitted that show the recommended alternate determined from the structure size and type analysis. See Section 14-2.01(03) for additional information regarding Stage 1 Plans requirements.

402-4.05 Preliminary Cost Estimate for Selected Alternate

A preliminary cost estimate shall be submitted for the recommended alternate determined from the structure size and type analysis. At this stage of development, for the computation of the initial capital cost, the recommended alternative shall have approximately 70 to 85% of the major-quantities pay items identified, including the pay item-numbers. The remainder of the items shall be included as a contingency item.

402-4.06 Miscellaneous Forms

A Quality Assurance form and a Scope/Environmental Compliance Certification/Permit Application form shall be provided with the submission. See Section 14-2.01(03) for additional information regarding necessary forms required with the Stage 1 Submission.

402-4.07 Computations

The necessary calculations performed during the structure size and type analysis shall be submitted. The following calculations are those that shall be included as part of the structure size and type analysis.

402-4.07(01) Structure-Sizing Calculations

The design computations for determining the structure size and geometrics for the alternates investigated shall be included. For a structure spanning a waterway, the waterway opening and freeboard calculations shall be included, along with the hydraulics-approval letter following the

Hydraulics Review Submission. All applicable and necessary drawings and sketches shall be submitted to supplement the structure-alternate sizing calculations.

402-4.07(02) Structural Calculations

The structural calculations performed during the structure size and type analysis will be included with the submittal. These can include preliminary structural-member calculations performed to obtain the required structure depth of the structure. If computer software is used, only the pertinent input and output shall be included in the submittal.

402-4.07(03) Quantities Calculations

The quantities computations for each alternate investigated during the economic analysis will be submitted, so that the results of the economic analysis can be verified. The preliminary quantities for the recommended alternate used to derive the preliminary cost estimate will be included with the submission.

402-5.0 PRIMARY EVALUATION FACTORS

402-5.01 Document Resources

402-5.01(01) Engineer's Assessment

The Engineer's Assessment is developed to establish the minimum parameters for the project as follows:

1. 3R or 4R criteria;
2. project alternatives and recommended alternate;
3. traffic maintenance;
4. cost estimates;
5. traffic data;
6. crash data;
7. survey requirements; and
8. right-of-way impacts.

402-5.01(02) Inspection Report

The National Bridge Inspection Standards dictate that every bridge is to be inspected at a frequency not to exceed 24 months. Inventory and condition data of all bridges is updated during biennial inspections in accordance with FHWA's *Recording and Coding Guide for the Structure Inventory and Appraisal of the Nation's Bridges*.

The inspection report includes inventory data such as:

1. location description,
2. bridge type,
3. geometric dimensions,
4. year built,
5. year reconstructed,
6. estimated remaining life,
7. condition ratings and comments,
8. pictures,
9. deficiencies identified, and
10. proposed improvements.

This information included within a bridge-inspection report can be a useful piece of information for a structure size and type analysis being performed for the replacement structure at a project location.

402-5.01(03) Site Reconnaissance

Site reconnaissance provides field information, changes from surveyed information, and project discussion with personnel from other offices and divisions.

402-5.01(04) Survey

Aerial and topographical surveys provide ground information of all physical features including utilities.

402-5.01(05) Hydraulics

Based on topographic-survey information, the Office of Hydraulics provides recommendations for the structure sizing. It provides Q_{100} and Q_{500} elevations, design flow, velocity, waterway

opening requirements, and scour information. See Section 203-3.04 for a typical hydraulics report.

402-5.02 Constraints

402-5.02(01) Environmental

The Environmental Services Division's Environmental Assessment Team will perform the environmental studies. A bridge over a waterway will likely require an IDEM 401 permit, ACE 404 permit, and Rule 5 permit. The following shall be considered in the analysis for structure-type selection.

1. Waterway Crossing. Number and location of piers.
2. Sensitive Area. Environmental impacts shall be minimized in a sensitive area, e.g., near wetlands.
3. Discharge of Fill. Discharge of fill below the Ordinary High Water elevation will require a U.S. Army Corps of Engineers Section 404 permit. The need for this type of permit will depend upon the amount and type of fill discharged.
4. Environmental Commitments. Project specific criteria and commitments.

402-5.02(02) Historic and Archeological Resources

Integrity of all residences, churches, bridges, or barns that are on or eligible to be on National Register of Historic Places must be maintained. *The Archeological Resources Protection Act (ARPA)* prohibits the excavation of archeological resources, or anything of archeological interest, on federal or Native American lands. Therefore, the project parameters may have to be altered to avoid impacting historic or archeological resources.

402-5.03 Costs

Costs of various alternates will determine the final recommendation. Initial and-life cycle costs are a truer indicator of the final cost.

Figure [402-5A](#) approximates the most economical structure for various span lengths. Factors such as vicinity of fabricators, availability, reliability of materials, and cost of labor shall also be considered.

402-5.04 Constructability

Temporary falsework may be a consideration in the structure alternate analysis and can be a substantial item of the construction cost. A superstructure system can include cast-in-place concrete. Therefore, it can require elaborate temporary supports and formwork. Such a system derives its economic feasibility from the relative simplicity of construction, or from the highly effective monolithic nature of the finished superstructure. If the bridge is over a waterway or will have a high finished elevation, the cost of the falsework may become prohibitive, and therefore eliminate this alternate.

A reduction below the minimum vertical highway clearance during construction is not permissible without a design exception. For a 3R non-freeway project, the minimum vertical clearance value is documented in the appropriate geometric design criteria table shown in Chapter [55](#), under Existing Overpassing Bridge. For another type of project, coordination is required with the appropriate district traffic engineer. A design-exception request shall be processed.

A cofferdam or temporary causeway can be another substantial item of the construction cost. These are often necessary for the contractor to build the substructure and foundation units. These shall be considered during the permitting process, and can be a limiting factor in the obtaining of the permits. These factors shall be considered in the structure size and type selection process.

402-5.05 Railroad

Railroad geometric requirements shall be considered in the structure size and type selection for a highway bridge over a railroad. Chapter 413 provides specific requirements which will apply to the bridge design.

402-5.06 Utilities

The bridge design shall be consistent with utility-accommodation policies. These are documented in Chapter 104.

402-5.07 Other Considerations

402-5.07(01) Maintainability

Open or inadequately-sealed deck joints have been identified as the foremost reason for structural corrosion of structural elements by permitting the percolation of salt-laden water through the deck. To address this, a continuous deck, integral end bents, improvements in drainage, epoxy coatings, and concrete admixtures shall be considered. The *LRFD Specifications* also requires that reasonable access be provided where other means of inspection are not practical.

402-5.07(02) Adaptability

Nearly every superstructure type can be widened, but not with the same level of ease. A slab, deck on beams or girders, or system consisting of prefabricated concrete or wood elements each lends itself to such reconstruction. However, a large concrete box, through-type superstructure, or that with substantial wings does not. If a definite need for future widening exists, these latter structural types shall not be considered.

402-5.07(03) Context-Sensitive Solutions and Aesthetics

Transportation professionals and communities are working together to develop engineering solutions that fit the project setting. Identifying potential issues and opportunities in the preliminary scoping phase, early in the process, can help develop the best project solution possible within the available budget. Engaging stakeholders throughout the project-development process allows their input to be considered during the appropriate stages of the project, and helps to gain their cooperation and support. A successful project will satisfy the purpose and need while preserving the scenic, aesthetic, historic, and environmental resources native to the project location.

Each project shall employ a context-sensitive approach, while the resulting project solutions will vary according to the context. The INDOT policy and definition of CSS, and additional information about CSS appears on the website at

<http://www.in.gov/indot/div/projects/indianacss/index.html>.

LRFD Specifications Article 2.5.5 promotes uninterrupted lines, contours that follow the flow of forces, and the avoidance of cluttered appearances. The requirements regarding aesthetics have been prompted because many bridges have been exclusively selected and designed on the basis of construction cost or engineering simplicity with disregard for their appearance and for their conformance with the environment. The bridge design shall integrate the basic elements of efficiency, economy, and appearance. Regardless of size and location, the quality of the structure, its aesthetic attributes, and the resulting impact on its surroundings shall be considered.

402-6.0 DESIGN FACTORS

402-6.01 Structure Location

The sizing of a structure is dependent on the features being crossed, roadways, railroads, waterways, or a combination of these. The key features that shall be addressed for each type of crossing are described below.

402-6.01(01) Stream Crossing

Approval by the Office of Hydraulics will be required prior to the submittal of Stage 1 plans for each waterway crossing. The requirements for the hydraulics submittal are defined in Section 203-3.04.

Chapter 203 provides criteria for the hydraulic design of a bridge waterway opening. This will have an impact on the size and elevation of the structure. Chapter 203 also discusses hydraulic policies on maximum backwater, freeboard, bridge sizing policy, maximum velocity, hydraulic scour and the use of analysis methodologies. The structural considerations relative to waterway opening are described as follows.

1. Substructure Displacement. An allowance has already been made in the required waterway opening provided by the Office of Hydraulics Team for the area displaced by the substructure. Therefore, the area of piers and bents below the Q_{100} elevation shall not be deducted from the gross waterway area provided. The Office of Hydraulics shall be contacted if thicker substructure units, e.g. drilled shafts, or if more substructure units are proposed than anticipated by the Office of Hydraulics so that adjustments can be made to the required waterway-opening value.
2. Existing Substructure Elements. Removing existing pier or abutment footings can be a major expense. Therefore, where practical at a stream crossing, the span lengths shall be

adjusted, or the entire structure shall be shifted so that new foundations or piles for the replacement bridge will avoid existing substructure elements.

3. Interior Supports. For a major waterway crossing, and if the foundation conditions allow, a single round, hammerhead-type pier supported by a deep foundation is preferred. Multiple round columns may be used, but they can require a solid wall between columns to avoid the collection of debris. A single-wall pier aligned parallel to the flood flow direction can be a more suitable alternative.

For a meandering river or stream, the most desirable pier type is normally a single, circular pier column.

4. Freeboard. Where practical, a minimum clearance of 2 ft shall be provided between the design water-surface Q_{100} elevation and the low-structure elevation to allow for passage of ice and debris. Where this is not practical, the clearance shall be established based on the type of stream and level of protection desired. For example, 1 ft shall be adequate for a small stream that normally does not transport drift. An urban bridge with grade limitations may not provide freeboard. A freeboard of 3 ft is desirable for a major river which is known to carry large ice floes or debris. Coordination with the Office of Hydraulics is essential.
5. Low Channel-Clearing Elevation. The low channel-clearing elevation shall be set as described in Section 203-3.04, normally at 1 ft above the Ordinary High-Water elevation. The OHW elevation shall be obtained from the survey or determined from U.S. Army Corps of Engineers procedures.
6. Span Lengths. The minimum span length for a bridge with more than 3 spans shall be 100 ft for those spans over the main channel. A three-span bridge shall have the center span length maximized where debris may be a problem. A two-span bridge shall be avoided at a stream crossing where the pier will be located in the center of the main channel. The Office of Hydraulics shall be contacted if a two-span structure is necessary.

402-6.01(02) Grade Separation

The geometrics of an underpass have an impact on the size of the overhead structure. Figures [402-6A](#), [402-6B](#), and [402-6C](#) provide schematics of a bridge underpass. The underpass shall be designed to satisfy the geometric design criteria described in Chapter [53](#) and as discussed in Section [402-6.02\(01\)](#). The geometric design of a bridge underpass is summarized as follows.

5. The full-approach-roadway section, including the median width, shall be provided through the underpass section.
2. The roadside clear-zone width applicable to the approaching roadway section and auxiliary lanes will be provided through the underpass.
3. Other roadside safety criteria may apply. See Chapter 49.
4. A collision wall to protect the bridge substructure from vehicular impact may be warranted through the underpass. The *LRFD Bridge Design Specifications* discusses both the warrants for and the design of a collision wall. See *LRFD* 3.6.5.
5. In determining the cross-section width, the likelihood of future roadway widening shall be considered. Widening an existing underpass in the future can be expensive, so it may be warranted, if some flexibility is available, to allow for possible future roadway expansion.

402-6.02 Structure Sizing

The sizing of a structure requires the evaluation of other factors in addition to structural considerations. These include bridge and underpass geometrics, abutment dimensioning, and waterway opening. Together, they will determine the overall size of the structure for analysis and design. Each structure of longer than 20 ft in total span length is considered a bridge, and must have a structure file number and a separate Des. number.

Chapter 53 provides criteria for roadway geometrics. The road-design criteria will determine the proper geometric design of the roadway, and the bridge design will accommodate the roadway design across each structure within the project limits. This will provide full continuity of the roadway section for the entire project. This process will, of course, require proper communication between the road designer and bridge designer to identify and resolve problems.

The bridge geometrics will be determined in the project scope of work. For a new or reconstructed bridge on a 4R project, the criteria provided in Chapter 53 will determine the geometric design of the bridge. For a bridge within the limits of a 3R project, the criteria provided in Chapter 55 will determine the bridge geometrics. Chapter 53 provides project scope-of-work definitions and a map of the State highway system with designated 3R and 4R routes.

402-6.02(01) Cross Sections

Figures [402-6D](#), [402-6E](#), [402-6F](#), and [402-6G](#) each provide schematics of the bridge cross section for a specific highway type. The following will apply to the bridge cross section.

1. Bridge Clear-Roadway Width. The geometric-design-criteria figure in Chapter [53](#) for the appropriate functional classification provides this information for a new or reconstructed bridge within the limits of a 4R project. The geometric-design-criteria figure in Chapter [55](#) for the appropriate functional classification provides this information for a bridge within the limits of a 3R project. Figure [402-6H](#) shows the required bridge-railing and approach-guardrail offset based on AADT, 4R, and 3R project requirements.

Where a bridge clear-roadway width is permitted to be narrower than the travel lanes plus the effective-usable-shoulder width on each side, a guardrail transition, collinear with the bridge railing, shall be provided. Thereafter, the guardrail shall be flared at a 30:1 ratio until the guardrail length satisfies the length-of-need requirement or it intersects the approach guardrail. However, a continuous straight, without flare, run of guardrail is preferred for driving comfort and aesthetics. For this situation, the bridge clear-roadway width will nearly match the face-to-face guardrail width of the approach road section.

Chapter [53](#) discusses the design of a median for a long bridge with a sufficiently narrow median. Increased safety benefits can be realized in construction of a single structure. Depending on site conditions, a single structure shall be used rather than twin structures where the median width is approximately 30 ft or less on a freeway, or 20 ft or less elsewhere. The median width at an overpass shall match the median width on the approach.

For the median shoulders of a divided facility with two or more lanes in each direction, each bridge shall have a 5'-8" median-shoulder width where a type FC, FT, or TF-2 railing is used, or a 6'-0" median-shoulder width where another bridge-railing type is used. An auxiliary lane may be required across a structure where warranted. See Chapter [53](#) for the requirements.

2. Cross Slope. Each new or reconstructed bridge on a tangent section will be constructed with a cross slope of 2% sloping away from the crown. The 2% applies to the entire width from the crown to the face of railing or curb. The crown across the bridge will be in the same location as the approaching roadway crown. A tangent-section cross slope may be increased to 3 to 4%, with only one slope break in the deck, if roadway geometrics require it.

3. Sidewalk. Chapter [53](#) provides guidelines for sidewalk warrants and sidewalk requirements. Sidewalks are required on an overpass structure or on the road being overpassed if they are currently present, or if either roadway is a candidate for a future sidewalk according to Chapter [53](#). A pedestrian fence may be required (see Chapter 404).
4. Bridge Width for Traffic Maintenance. The figures in Chapter [53](#) provide criteria for the bridge width. Additional permanent bridge width may be provided solely for the purpose of placing one lane of traffic across the bridge during construction. This can eliminate the need for a detour or runaround, or the use of a local road to re-route traffic during construction. See Chapter [83](#) for more information on maintenance and protection of traffic during construction.
5. Bridge Width on Flat or Short Horizontal Curve. Railings and copings on a bridge within a horizontal curve are built concentric with the roadway centerline. However, where the bridge is on a flat curve, or if the bridge is short, it may be more practical to build the railing and coping parallel to the long chord if the curved roadway plus shoulders and barrier offsets is within the inner faces of the railings, and it is economically feasible to construct a wider tangent bridge deck. It is considered economical if the bridge-deck width is increased by not more than 1 ft. However, it can be increased if it is determined to be more economical. Figure [402-6 I](#) illustrates these criteria.

402-6.02(02) Alignment

The horizontal and vertical alignment will be determined for the overall roadway within the project limits, and the bridge will be designed consistent with the roadway alignment. See Chapter [53](#) for geometric-design criteria. The desirable horizontal and vertical alignment objectives are as follows.

1. Grade. A minimum longitudinal grade of 0.5% on the bridge is desirable. A flatter grade will be permitted where it is not physically or economically desirable to satisfy this criterion.
2. Vertical Clearance. The vertical clearance requirements are shown in Figure [402-6J](#). This clearance shall be provided for the elevation and alignment of the overhead structure. The vertical clearance is determined at the low-steel or -concrete member elevation. Figures [402-6A](#), [402-6B](#), and [402-6C](#) illustrate where the clearance is measured. Clearance shall be maintained across both the traveled way and the shoulders. The same minimum vertical clearance in the traveled way and shoulders is not required to

be maintained in the clear zone. However, a separate minimum vertical clearance is often necessary within the clear zone. For economy, the minimum vertical clearance shall not be exceeded by more than 6 in. unless project constraints require a higher clearance.

Consideration of the vertical and horizontal clearance during construction phases shall be considered in setting the profile of the bridge. See Chapter 83 for requirements during construction.

3. **End Bent.** The end-bent configuration impacts the required structure length and shall be accounted for in the sizing of the structure. The following will apply.
 - a. The clearance from the top of the berm to the bottom of the superstructure shall be at least 6 in., with a maximum of 1'-8". The minimum berm width is 3 ft. See Figure 402-6K.
 - b. Wingwalls will be required for each beam structure.
 - c. The spillslope for a water crossing is limited to a maximum of 2:1, except for a structure located within the backwaters of the Ohio River, where the spillslope is 3:1. For an overpass structure, the required crossed-roadway-section clear-zone width shall be considered in the setting of spill slopes.
 - d. Where utilizing MSE retaining walls at the end bents, adequate distance between the MSE retaining wall and the end bent shall be maintained. See *LRFD* 11.10.4 for more information.

402-6.02(03) Structure Width

Structure width, or out-to-out coping, derives from providing a bridge clear-roadway width as outlined in Section 402-6.02(01). Bridge railings, sidewalks, median, etc. shall be considered toward determining the required structure width.

402-6.02(04) Superelevation

If practical, a horizontal curve or superelevation transition shall be avoided on a bridge. A bridge may be superelevated if this results in a more desirable alignment on either roadway approach. If properly designed and constructed, a bridge will function adequately where this occurs.

On a superelevated roadway section, a break may be provided between the traveled way and high-side shoulder. However, on a superelevated bridge section, a constant cross slope shall be provided across the entire curb-to-curb or railing-to-railing width. If the bridge is within the normal superelevation-transition length where the pavement slope varies on either side of the profile grade, the superelevation-transition diagram shall be modified to provide a constant cross slope. See Figure [402-6L](#).

The approach roadway will include a shoulder with a cross slope different from that on the bridge. For example, the typical roadway-shoulder cross slope on tangent is 4%. It will be necessary to transition the roadway shoulder slope to the bridge deck slope in the field. Plan details are not required for this transition.

402-6.02(05) Structure Length

Structure length shall be determined by considering the vertical elevations and horizontal dimensions at the high coping. This is applicable to a superelevated bridge. See figures [402-6M](#) and [402-6N](#) for a structure-length calculation method.

402-6.02(06) Clear Zone

The geometrics of an underpass have an impact on the size of the overhead structure. The roadside clear-zone width applicable to the approaching roadway section will be provided through the underpass. Chapter [49](#) provides the clear-zone criteria, which are a function of design speed, traffic volume, highway alignment, and side slope. If an auxiliary lane is provided through the underpass, this impacts the clear-zone-width determination.

A collision wall to protect the bridge substructure from vehicular impact may be warranted through the underpass. The AASHTO *LRFD Bridge Design Specifications* discusses both the warrants and design of a collision wall.

402-6.02(07) Three Sided or Box Structure

The bridge definition outlined in Section [402-6.02](#) also applies to each three-sided structure, oversized box culvert, set of multiple box culverts, or set of multiple pipe structures. A large culvert having an opening width of 20 ft or less can also qualify as a bridge if the skew results in the span's measurement along the centerline of the roadway to be greater than 20 ft. If a three-

sided-structure span length for either the flat-top or arch alternate is longer than 20 ft as described above, it shall be regarded as a bridge.

402-7.0 SUBSTRUCTURE AND FOUNDATION

This Section discusses types of substructure and foundation systems, and it provides their general characteristics. This information shall be considered with the intent to select the combination of substructure and foundation which is suitable at the site to economically satisfy the geometric requirements of the bridge and to safely use the strength of the soil or rock present at the site.

The demarcation line between substructure and foundation is not always clear, especially for extended piles or drilled shafts. The foundation includes the supporting rock or soil and parts of the substructure which are in direct contact with, and transmit loads to, the supporting rock or soil. This definition will be used to the greatest extent possible.

A similar difficulty exists in separating substructure and superstructure where these parts are integrated. This Section will refer to each component or element located above the soffit line as part of the superstructure.

Chapters 408 and 409 discuss the design of foundations and substructure elements.

402-7.01 Foundations

The most economical design shall be established that accounts for structural criteria and intended function of the structure. Whether it is for shallow or deep foundations, the foundation support cost shall be defined as the total cost of the foundation system divided by the load the foundation supports in tons. The cost of a foundation system shall be expressed in terms of dollars per ton load that will be supported.

Most currently-used systems can be categorized into the groups illustrated in Figure [402-7A](#). These groups are discussed below.

For interior supports at a stream crossing, extended piles, piles with a pile cap, or drilled shafts are used. Where scour is not expected and quality load-bearing soil is close to the surface, the use of spread footings shall be considered, provided that the geometric limitation as discussed in Section [402-6.01\(02\)](#) is satisfied.

402-7.01(01) Pier or Frame Bent Supported with Spread Footing

Limiting the applied stress for a specified amount of settlement is the most controlling factor in the design of a spread footing. The *LRFD Bridge Design Specifications* provides no dimensional restrictions for substructure settlement for a spread footing. However, the design shall satisfy the geotechnical-report recommendations which are based on a specific amount of settlement. Unlimited settlement can impair the serviceability of the structure and can cause problems as follows.

1. The superstructure can intrude into the required vertical clearance. This can be prevented by increasing the as-built clearance to be in excess of the specified settlement value.
2. Rideability can be impaired by introducing angular rotations in the longitudinal profile of the roadway due to differential settlement among the individual substructure portions. The substructure design shall limit such angular rotations to 0.005 rad. This value shall be applied to the cumulative rotations between two adjacent spans. Differential settlement shall be determined by means of assuming alternating maximum and minimum values of the calculated settlement range between adjacent supports. Because settlement is a deciding factor, this calculation shall be made during the structure type and size determination. The limit of 0.004 rad in relative rotation shall be applied to either a simply-supported or continuous superstructure. For a fixed value of permissible rotation, the larger the span, the larger the settlement that can be accommodated.
3. In a continuous superstructure, differential settlement results in force effects which are in addition to those due to gravity loads. The *LRFD Specifications* incorporates both force and geometric effects of settlement in a number of load combinations which are mandated for investigation. It does not prohibit the inelastic redistribution of the resulting force effects.
4. The larger the span and the lesser its rigidity, the smaller are the force effects due to settlement. Where settlement causes negative moments in the superstructure, the problems that can arise are related to cracking and ductility, rather than to strength.

The *LRFD Specifications* address the danger of scour for a pier located in a waterway. *LRFD Specifications* Section 2 lists methods of minimizing this catastrophic potential, due to the large number of bridges that wash away each year. A spread footing requires a quality foundation material close to the ground surface. The bottom of a spread footing on soil shall be below the deepest frost level or at least 4 ft below the flow line. See Chapter 408 and its applicable figures for more information.

402-7.01(02) Pier or Frame Bent Supported with Deep Foundations

Where conditions are not present which favor or permit the application of a spread footing, a deep foundation, such as drilled shafts or piles, shall be considered. Prefabricated piles made of concrete, steel, or a combination of these, are driven into position by means of hammers. Drilled shafts and drilled concrete piles are constructed with the same technique requiring specific skills. Drilled shafts, especially those with bell-shaped bottoms, can carry extremely large loads.

The *LRFD Specifications* provides a two-level approach for the design of a deep foundation, in which the structural resistance of the pile or shaft and the structural resistance of the supporting soil or rock are investigated separately.

402-7.01(03) Extended-Pile Bent

Under certain conditions, the economy of a substructure can be enhanced by means of extending the deep foundation above ground level to the soffit of the superstructure. These conditions exclude the presence of large horizontal forces which can develop due to seismic activity, collision by vessels or vehicles, ice, or stream flow intensified by accumulated debris. Longitudinal braking forces, which are increased in the *LRFD Specifications*, shall be resisted at the abutment.

The extended piles require a cap-beam for structural soundness. This cap-beam may be an integral part of the superstructure. An extended drilled shaft placed directly beneath each beam line can eliminate the use of a cap-beam. Sufficient space shall be provided at the top of the shaft to allow for future jacking operations.

402-7.02 End Bent or Abutment

402-7.02(01) Usage

The types of end supports and their usage are as follows.

1. Integral End Bents. These, a subset of spill-through end bents, shall be used for a structure which is in accordance with the geometric limitations provided in Figure 409-2A. Integral end bents may be utilized where the structure configuration has the end bent behind and acting independently from a retaining wall such as a mechanically-stabilized-earth retaining wall.

2. Non-Integral End Bents. These shall be used where spill-through end bents or end bents independently placed behind a mechanically-stabilized-earth retaining wall are desirable, but integral end bents are not appropriate. These include semi-integral end bents and shallow end bents utilizing an expansion joint.
3. Abutments and Wingwalls. For soil conditions or bridge geometric dimensions not suitable for spill-through end bents, abutments and wingwalls of the cantilever type, or a mechanically-stabilized-earth wall or other type of earth-retaining system, shall be used.

See Chapter 409 for more information.

402-7.02(02) Spill-Through End Bent

A spill-through end bent, either integral or non-integral, by its nature is supported by an individual deep foundation, which the fill flows through. The end bent consists of a cap-beam and a non-integral mudwall which provides partial retaining for the fill at its top. With this type of end bent, the fill is largely self-supporting. Therefore, for the same fill slope, it requires more space in plan geometry and results in longer spans.

402-7.02(03) Integral End Bent

The integral end bent eliminates the deck joint between the superstructure and the end bent by the structural integration of the two. The vertical dimension of the cap beam can be minimized as the mudwall becomes a composite part thereof.

Components of the deep foundation shall be flexible to accommodate the longitudinal movement of the pile bent. Such flexibility can be provided with steel H-piles or steel-encased-concrete piles.

The reinforced-concrete bridge approach shall be attached to the end bent. The longitudinal bridge movements shall be accommodated at the outer end of the reinforced-concrete bridge approach by using a terminal joint of 2 ft width or a pavement relief joint if a portion of the adjacent pavement section is concrete. No such joint is required if the entire adjacent pavement section is asphalt.

The *LRFD Specifications* encourages minimizing the number of deck joints. This end-bent type satisfies that requirement. If the superstructure is fully continuous, no deck joints remain.

Because of the difference in construction costs between an integral end bent and an abutment, and the less-than-desirable performance of bridge-deck joints, an integral end bent shall be used where possible. See Chapter 409. Limitations of continuous superstructure length are related to the flexural stresses caused in the piles by the expansion and contraction of the deck due to temperature, creep, and shrinkage.

If the maximum distance from the zero point to the integral end bent does not exceed the criteria shown in Figure 409-2A, the effects of deck expansion and contraction may be neglected in the analysis of the bridge. The piles are designed only for axial loads to satisfy specified stress limits. If the continuous deck length exceeds these limits, or if a better understanding of the behavior of the end bent is desired, an in-plane frame analysis shall be performed and the components designed as specified in the *LRFD Specifications*.

To minimize deformation-induced force effects, only one row of vertical piles is permitted in an end bent. If the resistance of the surrounding soil is larger than a specified value, the piles shall be driven into predrilled holes, which will be filled later with uncrushed granular material as described in the *INDOT Standard Specifications*. This latter measure can be used effectively as the stiffness of the pile, hence the stresses are inversely proportional to the third power of the free-pile length.

Unless approved by the Director of Bridges, temperature movement shall not exceed the predetermined deflection limit at either end of a bridge supported with integral end bents.

402-7.02(04) Non-Integral End Bent

This consists of a semi-integral end bent or an end bent utilizing an expansion joint. This end bent type shall be used where an integral end bent is not feasible based on the criteria shown in Figure 409-1A. Further explanations of semi-integral-end-bent and expansion-end-bent usage are described in Chapter 409.

402-7.02(05) Abutment

A concrete abutment may be supported with either a spread footing or a deep foundation. It consists of a vertical stem which supports the superstructure by means of bearings with or without pedestals, or a mudwall which retains the embankment fill in the longitudinal direction of the bridge. It can support the end of a reinforced-concrete bridge approach. Wingwalls are

usually required to retain the fill in the transverse direction. Continuity of the riding surface between the abutment and the superstructure is provided by means of a deck joint.

For restricted geometry, a tall superstructure, or large relative longitudinal movement between the superstructure and the substructure, the abutment may be the only feasible alternative. It is, however, expensive to construct. For a small bridge, its cost can be out of proportion with respect to other components of the bridge. With large abutments located close to the edge of roadway or waterway below, superstructure spans can be reduced. Large abutments, however, can result in poor aesthetics of the bridge, and can impair visibility at an overpass.

An abutment is affected by the bridge geometry and site conditions. Therefore, it can be designed in an infinite variety of shapes and sizes. Figure [402-7B](#) indicates the parts of a typical cantilever abutment of rectangular layout supported with a spread footing. If the wingwalls are large, they can be directly supported with spread footings or footings with piles.

402-7.03 Pier or Frame Bent

The above-ground portion of a substructure can be categorized as illustrated in Figures [402-7C](#) and [402-7D](#). These are discussed below. See Section 409 for more information on interior supports.

402-7.03(01) Pier

A pier is made of reinforced concrete. Where piers are directly exposed to public view, their appearance may be improved as discussed in Section [402-5.07](#).

The round column shown in Figure [402-7C](#) detail (a) is the most economical, because it is structurally efficient and easy to construct.

The single, narrow wall shown in Figure [402-7C](#) detail (d) is most suitable if its structural height is relatively small and the superstructure is a concrete slab; if the superstructure is made of longitudinally placed, precast concrete components; or if it includes closely spaced, longitudinal beams. For a greater structural height, a hammerhead pier, as shown in Figure [402-7D](#) detail (b), either with a rectangular or rounded stem, is more suitable.

The use of twin walls shown in Figure [402-7C](#) detail (e) permits the segmental construction of a medium-span superstructure made from longitudinal precast concrete components without falsework. A larger pier located in a waterway susceptible to ice accumulation may be fitted

with a sharp icebreaker nose as shown in Figure [402-7C](#) detail (f). A medium- or large-span, single-box superstructure may be supported by means of aesthetically-pleasing flared piers, as illustrated in Figure [402-7D](#) detail (c). In a debris-prone stream, the wall-type pier is preferred.

402-7.03(02) Frame Bent

A frame bent, as shown in Figure [402-7E](#) can be constructed from steel, concrete, or a combination of these materials. Steel is used only for a temporary structure due to of problems associated with corrosion, the environmental impact of repainting, vulnerability to collision, and the difficulty in providing an appropriate pier head. Steel is not the most competitive material for resisting force effects which are primarily compressive.

A concrete frame bent shall instead be used to support steel or concrete structural members. The columns of the bent can be either circular or rectangular in cross section. Circular columns are usually more economical. The columns shall be directly supported by the slab portion of a spread footing or by the pile cap.

Figure [402-7E](#) detail (a) illustrates the most common type of concrete bent consisting of vertical columns and a cap beam, used in an overpass structure. Figure [402-7E](#) detail (b) depicts a tall concrete bent which can be used in a cable-stayed bridge. Concrete can provide an economical and visually attractive substructure.

402-8.0 SUPERSTRUCTURE

This Section discusses the considerations in the selection of the superstructure type.

402-8.01 General

The State's geography is relatively flat with predominately small waterways, therefore, the largest of the available bridge types is rarely appropriate. The bridge types provided in Figure [402-8A](#) are those which are either traditional or which may have an application resulting from the introduction of the AASHTO *LRFD Specifications*.

A minimum of four beam lines is required for a multi-beam application on a State route. The minimum deck thickness is 8 in., including a 1/2-in. sacrificial wearing surface.

The following provides guidance in selecting the bridge-superstructure type that is most appropriate for the highway geometry, span lengths, and site conditions.

1. Span Lengths. Figure [402-8B](#) indicates the typical ranges of span lengths for which each superstructure type will apply.
2. Superstructure Depth. See *LRFD* Table 2.5.2.6.3-1 for the traditional minimum depth for constant-depth superstructure for each structure type.
3. Superstructure Characteristics: Figure [402-8C](#) tabulates basic characteristics of the superstructure types shown in Figure [402-5A](#).

402-8.02 Superstructure Type

402-8.02(01) Type A: Reinforced Cast-in-Place Concrete Slab

The reinforced cast-in-place concrete slab is used because of its suitability for short spans and its insensitivity to skewed or curved alignments. It is the simplest among all superstructure systems, as it is easy to construct. Structural continuity can be achieved without difficulty.

Haunching is used to decrease maximum positive moments in a continuous structure by means of attracting increased negative moments to the haunches and providing adequate resistance at the haunches for the increased negative moments. It is a simple, effective, and economical way to maximize the resistance of a thin concrete slab. As illustrated in Figure [402-8D](#), there are three ways of forming the haunch. The parabolic shape (a) is the most natural in terms of stress flow, and the most aesthetic. It is preferred where the elevation is frequently in view. The parabolic haunch, however, is difficult to form and, as alternatives, the straight haunch (b) and the drop panel (c) shall be considered where appropriate. The narrow pile cap (d), used in conjunction with an extended-pile substructure, does not qualify as an effective haunch.

Figure [402-8E](#) depicts the elevation of a three-span, continuous-haunched slab bridge. The preferable ratio between interior span and end spans is approximately 1.25 to 1.33 for economy, but the system permits considerable freedom in selecting span ratio. The ratio between the depths at the centerlines of interior piers and at the point of maximum positive moment shall be between 2.0 and 2.5. Except for aesthetics, the length of the haunch shall not exceed the kL values indicated in Figure [402-8D](#), where L is the end span length. Longer haunches may be unnecessarily expensive or structurally counterproductive.

402-8.02(02) Type B: Longitudinally Post-Tensioned, Cast-in-Place Concrete Slab

The distinction between the type A and type B superstructures is the difference in how they are reinforced. Therefore, most of the information described above for type A is applicable.

A shallow post-tensioned slab can be a feasible structural system for a given situation. Structural analysis shows that if the haunch ratio is about 2.5, the ratio between maximum negative and positive moments is also approximately 2.5. This indicates that the amount of post-tensioning steel, as determined for positive moment, will be consistent with the requirements for negative moment, producing a balanced design. As an alternative, the right-hand side of the elevation in Figure [402-8F](#) is shown with a constant-depth soffit. The constant-depth soffit does not produce a balanced design; therefore additional negative-moment reinforcement is required. This results in a reduction in span range and increases the probability of spalling by providing a large amount of reinforcing steel close to the surface.

By increasing the span-to-depth ratio to a maximum of 1:30 for simple spans and 1:40 for continuous spans, cost savings can be obtained in both superstructure and substructure. The use of the potentially-extreme ratio shall be made with consideration, as appropriate, for deflection performance and dynamic response.

There are two alternatives for transverse steel. One is with normal reinforcement, for which the requirements are the same as for a type A deck system. The second alternative is shown in Figure [402-8G](#) which incorporates transverse post-tensioning. The cross section can be with or without cantilever overhangs. In the latter situation, two levels of post-tensioning instead of one can be used. As illustrated in Figure [402-8F](#), transverse tendons shall be fanned in the end zones of a skewed bridge. If the bridge railing is attached to a cantilever overhang at isolated points such as posts, both longitudinal and transverse reinforcement shall be provided therein. The problem that often rises with transverse post-tensioning on a deck of width of less than approximately 30 ft is the control of excessive seating losses, which makes the reinforced alternative preferable.

402-8.02(03) Type C: Longitudinally Post-Tensioned, Cast-in-Place Concrete Box Girders

This is a variation of type B, in which the deck system is considerably lighter and, therefore, more economical due to large, rectangular, and rhombic voids. This creates a multicell box-type superstructure, as illustrated in Figure [402-8H](#). This is often referred to as the California-type box girder. To facilitate the forming of a thin-walled box, the majority of these structures have a straight soffit. Consequently, considering longitudinal post-tensioning, this system is also unbalanced, requiring additional negative-moment steel. Full diaphragms are required at all interior piers and abutments. The preferred substructure type is the flared, rounded pier, which

provides direct support for the two internal webs and provides the potential for a solid transverse moment connection, if required for seismic force effects.

For type A, B, or D, concrete is placed to full depth in a single operation. For type C, it is poured in three stages. First, the bottom slab is placed with dowels for connecting the web reinforcement as shown in Figure [402-8H](#). Next, the web steel is assembled, to which the rigid tendon ducts are attached, and then the web concrete is placed between removable forms. The last step is to construct a form for the top slab, assemble its reinforcement, and pour the concrete. Thus, a large structure can be built without the need for expensive machinery, if it is close to firm ground.

The system is suitable for an alignment with moderate curvature and skew. The structure is analyzed with the piers as a framed spine beam to obtain moment, shear, and torsion. For the latter, this system offers excellent resistance.

402-8.02(04) Type D: Two-Way Post-Tensioned, Cast-in-Place Concrete Spine-Beam with Cantilevers

Type D is most suitable for an excessively curved or skewed alignment, and is insensitive to the location of its piers. The cross section is a variation of type B in which the application of large, cantilever overhangs reduces the weight of the superstructure. Above a certain structural depth, it becomes economical to further reduce the structure weight with round voids which are formed by means of stay-in-place steel pipes.

The voided deck has a tendency to crack at the top near the centerline of the voids. To prevent the formation of cracks in the bridge, the top is transverse post-tensioned. This transverse post-tensioning lends itself to the formation of large cantilever overhangs and, thus, a dual use. This improved version, with or without voids, is illustrated in Figure [402-8 I](#).

Considering span range, the type D system is a transition between the type B solid slab and type C cellular deck. Its cross section is not as effective as that of the cellular deck, but because its whole depth can be placed in one operation, it is less labor-intensive.

The largest void used is approximately 4 ft diameter, providing for a structural depth of approximately 5 ft. A narrow bridge, as illustrated in Figure [402-8 I](#), requires a minimum of two voids. As the core widens or the structural depth decreases, the voids will be more numerous but of lesser diameter. If the core-void ratio, with the area of the wings excluded, does not exceed approximately 30%, a solid cross section, as shown in Figure [402-8 I](#), shall be used. To be

economical, the void ratio shall be approximately 35%. If the ratio exceeds 40%, the *LRFD Specifications* considers the deck as a cellular, or box, construction.

For the piers, slender, round columns may be used. For a short bridge such as an overpass, the columns may be framed into the superstructure. For a longer bridge, sliding bearings shall be applied. A long structure with flat horizontal curvature requires intermittently-located wide piers with two bearings to provide torsional stability. A sharply-curved structure has a high degree of inherent stability, therefore, stabilizing by means of two bearings or a line support, is required only at the abutments.

402-8.02(05) Type E: Prestressed, Precast Concrete Beams

Precast, prestressed concrete I-beams were initially adopted as AASHTO types II, III, and IV. Later, types I, V, and VI were added to extend their span range at both the lower and upper ends of the spectrum.

Currently, the AASHTO I-beam types I, II, III, and IV are used, along with the bulb-tee beams for longer spans. Prestressed, precast concrete box beams are also acceptable for a shallow construction depth. However, they shall not be placed either partially or entirely below the Q_{100} elevation.

Figure [402-8J](#) illustrates a typical superstructure cross section with prestressed, precast concrete I-beams.

For a preliminary selection of an I-beam size and spacing, see Figure [402-8K](#), Prestressed Concrete I-Beam Selection Chart. The slab overhang shall be as wide as possible but shall be in accordance with the overhang criteria provided in Chapter 404.

For a wide beam spacing, if foundation conditions permit, the beams can be individually supported by means of drilled shafts, as shown in Figure [402-7A](#) detail (c), instead of a continuous pier cap.

Figure [402-8L](#) illustrates three variations of prestressed, precast concrete box beams. Alternative (a) is an open-box cross section. Its advantage over a closed box is in the forming of the beam. Alternative (b) is a closed, or spread, box, with a constant depth, cast-in-place deck. Alternative (c) is a keyed-in design. For transverse continuity of the deck, it shall have the top reinforcement shown, but not dedicated shear connectors. All three alternatives can have beam spacings of up to approximately 15 ft.

Precast beams shall be continuous in the longitudinal direction for transient loads. In this arrangement, the beams retain their individual bearings, but their ends are incorporated in a common diaphragm which is cast monolithically with the deck.

The reinforcement for flexural continuity is located in the deck. The strands are extended into the diaphragm to prevent separation at the bottom that can occur as a result of the upward bowing of the prestressed beam due to creep. The tendency for creep can be minimized by permitting the beam concrete to mature prior to placing the deck. The extended strands also increase the shear resistance of the prestressed beams.

This system is adaptable without regard to skew. Horizontal curvature cannot easily be matched with a continuous structure, but only by means of a series of chorded spans laid out in a segmental form.

402-8.02(06) Type F: Bulb-Tee Beams Made Continuous by Means of Post-Tensioning

Precast beams can be made continuous for both permanent and transient gravity loads by means of the application of longitudinal post-tensioning. However, the scheme is provided herein in conjunction with the bulb-tee because it appears to offer the best structural efficiency for this type of construction with reference to its large bottom flange required to resist high negative moments in compression. This efficiency is achieved by means of a certain level of sophistication in construction technology which is within current practice, but not uniformly practiced nationwide.

Figure [402-8M](#) illustrates the cross section of the Indiana bulb-tee beam. In addition to making the beam structurally effective, the wide top flange provides lateral stability, reduces the deck area to be formed, and furnishes a safe and comfortable walkway for the construction crew. The limits of practical hauling shall be considered from the plant to the work site in selecting span length and beam type and size. Fabricators shall be contacted early in project development for information regarding the feasibility of hauling to a specific site.

The trajectory of the tendons follows that shown in Figure [402-8N](#). The draped tendons shall be as close as practical to the outer fibers of the beam, as the structural effectiveness of a tendon is directly proportional to the vertical distance between its highest and lowest points. If the sidespan is identical with the internal one and if the end is butted by another structure, the tendon anchorages may be located in the top of the beam. This increases tendon efficiency to avoid congestion. See Figure [402-8N](#). In either situation, an end-block at the anchorage end of the end beam will be required. One structure shall not include more than four continuous spans.

Figure [402-8 O](#) illustrates an intricate but convenient system of relatively large spans built from transportable, precast bulb-tee elements. The span element is the same as discussed above. The pier element is also the bulb-tee cross section but with a haunched soffit for improved negative-moment effectiveness. To avoid temporary falsework, thin-walled twin piers, as shown in Figure [402-7C](#) detail (e) may be used. For temporary stability, each set of pier elements shall be joined together with four diaphragms and the deck. The span elements and the deck above them shall be constructed with two-stage post-tensioning. Both systems accept unlimited skew but no curvature.

402-8.02(07) Type G: Deck System with Prestressed, Precast Longitudinal Elements

Prestressed, precast concrete longitudinal members of various cross sections have been used to create a bridge deck. The performance of these deck systems has not always been desirable due to the disintegration of longitudinal shear keys between the members. The keys, unprotected by transverse pressure, become vulnerable due to shortening and warping of the prestressed members, and they fail to transfer live-load shear. This results in potential overloading of the members and in an irresolvable maintenance problem for the deck.

The beneficial effect of keeping the keys under transverse pressure had been recognized previously, and third-point transverse post-tensioning had been introduced as an option. Unfortunately, the combination of low prestress, the unmatched side surfaces of the members, and the quality of the keys, has rendered this improvement ineffective. The grout in the key is impossible to inspect due to the way the key is formed.

LRFD Specifications Article 5.14.4.3 requires a keyway joint of not less than 7 in. depth between the members. In lieu of the traditional key, the *LRFD Specifications* prefers a V-shaped joint which is easy to fill and convenient to inspect. The post-tensioning ducts shall be located at the mid-depth of the joint, and not at the mid-depth of the beam. The minimum transverse prestress across the joint is 250 psi, or 20 kip/ft of length, which is a force nearly twice the traditional value. If the deck is not transversely post-tensioned, it requires a structural overlay depth of not less than 4.5 in.

The current practice is as follows.

1. Precast members have a composite structural-concrete overlay with a minimum depth of 5 in.
2. Precast members are transversely post-tensioned whether or not a structural overlay is used.
3. A traditional trapezoidal key is used instead of a V-shaped key.

4. The wet-joint depth between elements is 8 in.

As illustrated in Figure [402-8P](#), there are four precast, prestressed concrete members which can be economically assembled into a simply-supported deck system. In descending order of span length, these are the single tee, the double tee, the box, and the solid slab. The *LRFD Specifications* also includes channel sections, but these will herein be considered as a double tee with truncated cantilever overhangs. The precast members either serve as the finished roadway or provide an uninterrupted formwork for a structural-concrete overlay.

The sections' depth of the top flange, d , shall not be less than 6.5 in. if post-tensioned, and not less than 4 in. if overlaid. If the member is transported by truck, its width shall not exceed 8 ft. There is an incentive to decrease the number of joints in the deck, but this results in larger members. The transportability and erectability of the members shall be investigated considering both weight and geometry, early in project development, with potential contractors. Although the double tee has a less than perfect cross section considering structural efficiency, this is offset due to ease of forming.

For simplicity, only the box alternative is shown for the two methods of assembly as outlined above. Figure [402-8Q](#) is applicable to all four sections. For a box or slab section, end diaphragms are not required. For a single- or double-tee section, end diaphragms are required. Since it is nearly impossible to manufacture perfectly matched precast members, the surface of the grouted and post-tensioned deck shall be ground, where necessary. For this, the minimum specified depth of the top flange shall be increased by 0.5 in.

No variation of this system is applicable to a curved alignment. Skew is possible, but forming and casting the ends of each member with an angle of other than 90 deg will cause difficulty in manufacturing. The desirable limit for skew is 30 deg. A skew angle of greater than 45 deg not permitted. This system can also be made continuous in the longitudinal direction by using a monolithic diaphragm and continuity steel or longitudinal post-tensioning similar to precast-concrete beams discussed above. A double tee, however, which lacks an effective bottom flange, requires other measures to improve the compressive strength of the stems at the point of junction.

402-8.02(08) Type H: Segmental Concrete Box

The use of a segmental concrete structure may be considered for the following:

1. a bridge with long spans;
2. a long bridge with medium-length spans and limited vertical and horizontal curvature designed with essentially identical precast segments; or

3. a sharply-curved bridge where cast-in-place operations are not permitted.

The metal formwork, especially built for each construction, is expensive, and one of the above considerations shall be used to justify the use of this structure type.

Figure [402-8R](#) illustrates a typical cross section with a single cell. This type of superstructure has its own technical literature with reference to long spans. A summary appears in the *AASHTO Guide Specifications for Design and Construction of Segmental Concrete Bridges*. The segments can be assembled by means of either span-by-span or balanced-cantilever methods, using either precast or cast-in-place concrete segments. The preferred method of longitudinal post-tensioning is by means of internal bonded tendons. However, longitudinal post-tensioning with unbonded tendons is also permitted. These are threaded through deviation blocks and anchored in the diaphragms of the adjacent spans. To avoid longitudinal cracking, the top slab shall be transversely post-tensioned.

The segmental interfaces shall be match-cast and shall include shear keys, which shall be bonded with epoxy adhesive.

402-8.02(09) Type I: Composite Steel Rolled Beam

Low structural depth, thick webs, and wide flanges characterize most of the steel beams rolled today. Therefore, most of these beams are considered compact sections that do not require intermediate web stiffeners and require minimum lateral support. They are not economical based only on least steel weight. Instead, economy is derived from low fabrication costs and minimal or sometimes nonexistent wind or sway bracing. Spacing of diaphragms shall be in accordance with Chapter 407.

The depth-to-span ratio for the beam plus slab shall not exceed 1:24 for simple spans or 1:33 for continuous spans. For continuous spans, the span is the distance between points of dead-load contraflexure.

Cover plates for rolled beams are prohibited on the flanges. Weathering, or unpainted, steel shall be used to lower the future maintenance cost. See Chapter 407 for steel-weight curves, which can be used to provide a preliminary estimate of steel weight. With proper diaphragms, this structure type is suitable for a skewed or horizontally-curved alignment. See Chapter 407 for more information.

See Figure [402-8 S](#) for a typical steel rolled beam section.

402-8.02(10) Type J: Composite Steel Plate Girder

Steel plate girders may be used in lieu of steel rolled beams for spans that are uneconomical, or not feasible, for that type of structure. The depth-to-span ratio for the girder plus slab shall not exceed 1:20 for simple spans or 1:28 for continuous spans. For continuous spans, the span is the distance between points of dead-load contraflexure. Weathering, or unpainted, steel shall be used to lower the future maintenance cost. See Chapter 407 for steel-weight curves, which can be used to provide a preliminary estimate of steel weight.

It is seldom economical to use the thinnest web plate permitted by *LRFD*. The use of a thicker web and few or no intermediate transverse or longitudinal stiffeners shall be investigated. For appearance, transverse stiffeners shall be located on the inside of the outside girders. With proper diaphragms, this structure type is suitable for a skewed or horizontally-curved alignment. See Chapter 407 for more information.

See Figure [402-8T](#) for a typical composite steel plate girder section.

402-8.02(11) Type K: Composite Open Steel Box Girder

Single steel box girders, usually closed on the top due to an orthotropic steel deck, are used for large spans which are rarely required. As illustrated in Figure [402-8U](#), the lack of fatigue-prone sway and wind-bracing connections make the open steel box less susceptible to fatigue damage, and the use of two girders as a minimum is permitted. This system is adaptable to a curved alignment and where the available structural depth is limited. Moderate skew causes no problems.

During transportation and construction, the open box can require sway and internal, or wind, bracings. The mechanically-connected sway bracings shall be removed after construction. If too much torsional rigidity is provided to the boxes, they can cause longitudinal cracking in the slab, especially if the slab had been empirically designed. A minimum of two bearings per girder shall be used to provide adequate torsional resistance. A solid diaphragm with an access hole shall be placed at all bearing points.

Transverse web stiffeners may be used, but the use of longitudinal web stiffeners shall be avoided.

402-8.02(12) Type L: Wood Superstructure

The use of a wood superstructure is limited to a low-volume, local road, and is subject to the approval of the Director of Bridges. See Chapter 413. A wood bridge can be an attractive alternative for a small span or a temporary bridge. Wood can be used either as a deck and or can be directly supported by wood trestles, or piers.

As illustrated in Figure [402-8V](#), there are two variations for use as a deck unsupported by other components. The deck may be constructed from wood panels, prefabricated either by gluing or spiking, which are of full-span length and are connected together by means of bolting spreader beams to the underside of the panels at intervals not exceeding 8 ft. The *LRFD Specifications* permits the use of this type of deck without spreader beams, but its use is not recommended. The deck shall have an asphaltic wearing surface. Because the use of this deck is limited to simply-supported spans, it is recommended for a rural or secondary road where a rectangular layout can easily be achieved.

Alternatively, the deck can be constructed from prebored longitudinal laminates which are laid out in a staggered design and assembled by means of transverse post-tensioning. The laminates are held together by means of interface friction, and no other fasteners are required. To improve rideability and surface friction, the use of an asphaltic surface treatment is mandatory. The system lends itself to continuous construction with limited curvature, but with unlimited skew.

Two other alternatives are also available for a transversely post-tensioned wood deck. One includes glued wood ribs, by which the flat deck is transformed into a series of tee-beams. The second is an extension of the first by the addition of a post-tensioned bottom flange by which a cellular cross section is created.

Either flat deck can also be used as a transversely-positioned slab supported with longitudinal beams. The post-tensioning will run longitudinally in the laminated deck.

As illustrated in Figure [402-8W](#), wood can be used also as a primary longitudinal component as either sawn or native, in closely-spaced stringers or widely-spaced glue-laminated beams. For composite construction, the concrete slab shall be keyed into the top of the wood component and secured with spikes. Both alternatives permit skew, but neither permits curved alignment or continuous construction.

402-8.02(13) Type M: Structure Under Fill

This type of structure can be an attractive alternative for a small stream or ditch crossing, a minor highway or street crossing, or a pedestrian or animal crossing. This type of structure may be made of steel, aluminum, or concrete. The most common configurations used are the three-sided

concrete or steel structure, four-sided precast concrete box structure, structural plate pipe arch, or circular pipe.

The structure-sizing process is performed in accordance with a priority system. This system consists of six trials where specific installations are considered prior to evaluating other structure types, such as a reinforced cast-in-place concrete slab. The design priority system is as follows:

Trial 1: single circular-pipe installation.

Trial 2: single deformed-pipe installation.

Trial 3: single specialty-structure installation.

Trial 4: multiple circular-pipe installation.

Trial 5: multiple deformed-pipe installation.

Trial 6: multiple specialty-structure installation.

The principles of the priority system are summarized below.

1. A pipe structure is preferred to a precast concrete box section, precast concrete three-sided structure, or structural plate arch.
2. A circular pipe is preferred to a deformed pipe.
3. A single-cell installation is preferred to a multiple-cell installation.

See Chapters 202 and 203 for more information on the culvert-sizing process and the pipe-material-selection process. For pipe-material selection, use the Pipe Material Selection Software discussed therein. Additional considerations and design criteria for each type of buried-structure system are provided in *LRFD Bridge Design Specifications*, Section 12.

If a single or multiple specialty-structure installation is selected, manufacturers of such structures shall be contacted. See Section [31-4.05](#) for more information.

402-9.0 ALTERNATIVE DESIGN PROCESS

For a bridge project with an estimated construction cost of over \$10 million, the project manager and the designer shall investigate the possibility of performing a dual set of contract documents for two different structure types. The additional design fees for performing dual designs are minor in comparison to the results of a competitive contract letting. Designs for alternative structures shall be of equal safety, serviceability, and aesthetic value. Similarly, for foundations whose construction costs are expected to exceed \$2 million, the project manager and the designer shall investigate the possibility of performing a dual set of foundation contract documents.

402.10 ACCELERATED CONSTRUCTION

The concept of accelerated construction is increasing in popularity and frequency of use. If it is determined that a project can benefit from an accelerated-construction method, this shall be coordinated with the project manager. This type of construction shall be evaluated individually for each project, and shall not be considered for each structure size and type analysis.

Material	Superstructure Type	Typical Span Length (ft)
Precast Concrete	3-Sided Structure	12 – 48
Cast-in-Place Concrete	Continuous Reinforced Slab	20 – 45
Prestressed Concrete	Box Beams, Depth 12 in. through 27 in.	30 – 60
	Box Beams, Depth 27 in. through 42 in.	60 – 85
	I-Beams, AASHTO Type I	35 – 50
	I-Beams, AASHTO Type II	40 – 65
	I-Beams, AASHTO Type III	55 – 85
	* I-Beams, AASHTO Type IV	70 – 110
	Bulb-T Beams, Top-Flange Width 48 in. or 60 in.	80 – 140
	Bulb-T Beams, Top-Flange Width 49 in. or 61 in.	65 – 165
	Post-Tensioned Bulb-T Beams	140 – 200
	Post-Tensioned Slab	50 – 80
Structural Steel	Steel Rolled Beams	< 100
	Steel Built-Up Plate Girders	> 70

* These are generally used only in rehabilitating a structure. Bulb-T beams are preferred for a new or replacement structure.

		3. Stringers	Good	No	OK	No	Good	OK	OK
		4. Glulam beams	Good	No	OK	No	Good	OK	OK
M	Structure under fill	N/A	OK	Good	OK	No	Good	Good	Good

* Expensive if painted. Good if unpainted.

SUPERSTRUCTURE CHARACTERISTICS

Figure 402-8C

TYPE A, REINFORCED CONCRETE SLAB SUPERSTRUCTURE

Figure 402-8D

(a) PARABOLIC

(b) STRAIGHT

(c) DROP PANEL

(d) CAP BEAM *

* This configuration should not be used as a structural haunch.
