

# INDIANA DEPARTMENT OF TRANSPORTATION

*Driving Indiana's Economic Growth*

## ANNUAL AVERAGE DAILY TRAFFIC (AADT) ESTIMATES

The Indiana Department of Transportation (INDOT), through its Traffic Monitoring Section, collects, summarizes and interprets information on the traffic traveling on the state's highway system. The data is used to assess transportation needs, system performance and to develop highway planning and programming recommendations. Traffic data also plays a very important role in route planning and in the design of highway projects.

To collect this information, the Department operates two traffic monitoring systems:

1. A Statewide Traffic Monitoring System consisting of 110 permanent continuous count stations that collect volume, speed and vehicle classification data 24 hours per day, 365 days per year. Fifty of these sites also utilize weigh-in motion (WIM) technology to collect continuous truck weight data. These sites are located throughout the state to monitor overall traffic trends. Information from these counters is used to determine ANNUAL TRAFFIC GROWTH trends as well as develop AXLE, WEEKDAY and SEASONAL adjustment factors used with the state's coverage count program to determine estimates of annual average daily traffic (AADT).
2. The statewide coverage count program utilizes portable pneumatic road-tubes traffic counters to collect 48 hour traffic counts on all State Highway System traffic sections and in rural and small urban areas and all highway performance monitoring sections (HPMS). The coverage count program operates on a three-year cycle, counting one-third of all sections annually, or approximately 10,000 of the 30,000 count sites. Where possible, portable classifiers are used so that approximately 65% of all coverage counts collected are classification counts. Additional counts are taken within this program to support specific state projects. INDOT is transitioning the coverage count data collection from a central office operation to the 6 INDOT districts. In addition INDOT also contracts with 3 Metropolitan Planning Organizations (MPOs) to collect coverage count data within their areas.

## ADJUSTMENT FACTORS

Adjustment factors are necessary to convert an Average Daily Traffic (ADT) volume into an Annual Average Daily Traffic (AADT) estimate. Depending on the type of counter, the seasonal period of the setting, multiple factors may be necessary. These include axle, weekday and seasonal adjustment factors. For the 2/3's of the system not counted in the current year, the previously derived AADTs can be adjusted to the current year by utilizing the annual growth factors.

### **AXLE ADJUSTMENT FACTORS**

There are times when portable classifiers cannot be set due to number of lanes or the lack of free-flow speeds. In these cases, portable traffic counters utilizing single pneumatic road-tubes stretched across a lane or roadway are used. These types of counters register two axle impacts as one vehicle so when vehicles with three or more axles cross the road-tube they will be counted as multiple vehicles. Whenever possible axle adjustment factors should be developed from vehicle classification counters set on the same route within the vicinity of the axle counter and during the same relative time period. If this is not possible then the use of these factors applied by functional classification and volume groups are deemed acceptable.

### **WEEKDAY ADJUSTMENT FACTORS**

The purpose of these factors is to normalize the variability of traffic counts that exists between counts taken during the weekday, Friday, Saturdays and/or Sundays. In developing the weekday factors we found no significant statistical difference in the Monday through Thursday trends and for this reason combine these into a weekday factor. This is further justified as counts taken for INDOT will usually span a Monday through Wednesday or a Tuesday through Thursday count period.

### **SEASONAL (MONTHLY) ADJUSTMENT FACTORS**

Seasonal or monthly adjustment factors convert average daily traffic (ADT) to annual average daily traffic (AADT). Observed traffic volumes at a location often vary from month to month with higher summer traffic volumes and lower winter traffic volumes. To compare traffic volume data collected in different months, seasonal adjustment factors must be applied. The ADT is multiplied by the seasonal factor to obtain the AADT value. The continuous counter sites are grouped into five major factor groups (FG). Currently there are two urban factor groups and three rural factor groups which are based on grouped functional classifications.

### **ANNUAL GROWTH FACTORS**

As not all road sections are counted each year, there are times when previous years AADTs will need to be factored in order to estimate current year values. Annual Growth Factors are used in these situations and are developed by comparisons of previous years AADTs at INDOT's 110 continuous counting telemetry sites and averaged for the five factor groups (FG).

## AVERAGE AXLE ADJUSTMENT FACTORS (2004-2007)

Urban - Interstate (11), Freeways and Expressways (12)

*Note: Factors in this table are used to adjust previous year AADTs to a more current year for similarly classed roads (e.g. to adjust a 2004 urban interstate AADT to a 2007 equivalent, you would multiply the 2004 AADT by 1.085). This table is completely updated and supersedes any previous listing of year-to-year adjustment factors.*

### Example - Average Day-Of-Week Variation by Month for 2007

FG= 14: Urban Principal Arterials (14), Urban Minor Arterials (16) and Urban Collectors (17)  
(14 telemetry sites)

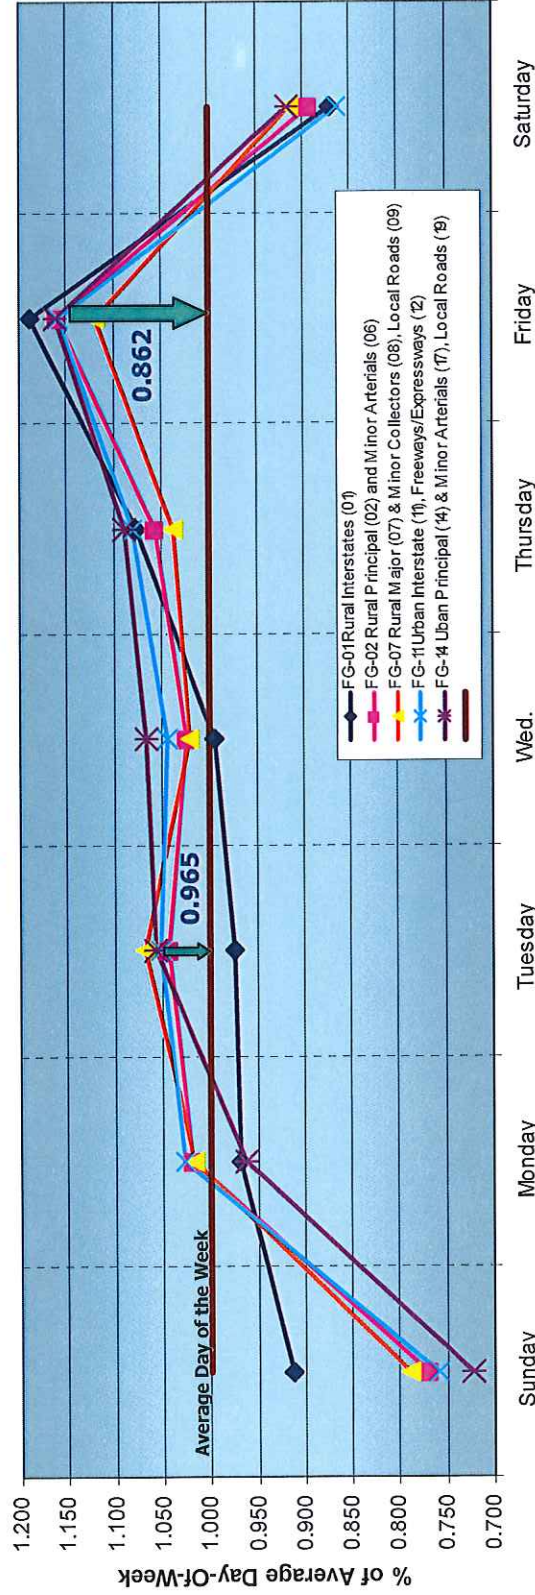

In developing the weekday factors no significant statistical difference in the Monday through Thursday trends were found to exist and for this reason have been combine into a "weekday" factor. This is further justified as counts collected for INDOT will usually span a Monday through Wednesday or a Tuesday through Thursday counting period (48 hours).

## Example - Day-Of-Week Variation for APRIL-2007 (all factor groups)

The purpose of these factors is to normalize the variability of traffic counts that exists between counts taken during the Weekday, Friday, Saturdays and/or Sundays.

In this example the two classification counts were taken in April 2007 on a road classified as Urban Minor Arterial (FG-14), one during the weekday (Monday-Thursday) with a count of 7640 and one on Friday with a count 9360:

Example:

$$\text{Count} * \text{Axle Factor} * \text{DOW Factor} = \text{ADT}$$

$$7640 * 1.000 * 0.965 = 7370 \text{ ADT}$$

$$9360 * 1.000 * 0.862 = 8070 \text{ ADT}$$

## Example - Seasonal Adjustments

Seasonal or monthly adjustment factors convert average daily traffic (ADT) to annual average daily traffic (AADT).

Observed traffic volumes at a location often vary from month to month with higher summer traffic volumes and lower winter traffic volumes. To compare traffic volume data collected in different months, seasonal adjustment factors must be applied. The ADT is multiplied by the seasonal factor to obtain the AADT value.

Example1: ADT: 35,200 Count taken February 2007  $35,200 * 1.183 = 41,640$  AADT  
 Example2: ADT: 46,420 Count taken July 2007  $46,420 * 0.897 = 41,640$  AADT
